

# A Vignette/Tutorial to use ResistanceGA

*Bill Peterman*

*2017-03-16*

## ResistanceGA: An R Package for Optimizing Resistance Surfaces using Genetic Algorithms

### Background

With this vignette/tutorial, hopefully you'll get an idea of what each of the functions in this package can do, as well present an example (using simulated data) of how you can optimize resistance surfaces in isolation as well as simultaneously to create novel resistance surfaces. This 'package' (I use that term very loosely) has largely been developed from functions I wrote to conduct different landscape genetic analyses. See Peterman et al. (2014) for the original conception of optimizing resistance surfaces using optimization functions. This approach was limited to optimization of continuous surfaces in isolation. Since that paper, I've further developed the optimization method to utilize genetic algorithms, implemented using the `ga` function from the GA package in R. By moving to genetic algorithms, much more complex parameter space can be effectively searched, which allows for the optimization of categorical resistance surfaces, as well as optimization of multiple resistance surfaces simultaneously. An application of the simultaneous optimization of multiple surfaces can be seen in Ruiz-Lopez et al., 2016.

This package fills a void in the landscape genetics toolbox. There are various methods proposed for determining resistance values (reviewed by Spear et al., 2010). Previously utilized methods generally searched a limited parameter space and/or relied on expert opinion. Graves et al. (2013) utilized optimization functions and interindividual genetic distances to determine resistance values, but found that the data generating values were rarely recoverable. I have not assessed the ability of functions/methods utilized in this package to optimize resistance surfaces as in Graves et al. (2013), but do note that very different methods of scaling, transforming, and combining resistance surfaces are utilized in **ResistanceGA**.

A few words of caution. I have made every effort to run and test each function with simulated data, but I make no guarantees concerning function performance and stability. Data formatting can be a challenge, and I have tried to simplify the process as much as possible. If you choose to optimize using CIRCUITSCAPE, Please make sure you carefully read through the CIRCUITSCAPE documentation, as well as other relevant papers by Brad McRae to get a more complete understanding of resistance modeling and circuit theory. If errors occur, start by making sure that you are providing function inputs in the correct format. If a function does not work, there likely will **not** be a useful error message to help you troubleshoot. Depending on interest and use, these are features that may be added in the future. Lastly, this is not a fast process. Even with the 50x50 pixel simulated landscapes used in this tutorial, each (CIRCUITSCAPE) optimization iteration takes 0.75–1.00 seconds to complete (Intel i7 3.4 GHz processor, 24 GB RAM). Optimizing using least cost paths is ~3x faster than with CIRCUITSCAPE. To further reduce optimization time when using least cost paths, the optimization can be run in parallel. It appears that under most circumstances the resolution of the landscape can be reduced without loss of information (McRae et al., 2008). As of version 3.0-1, it is possible to optimize with CIRCUITSCAPE on Linux, which allows for CIRCUITSCAPE to be run in parallel. This may reduce optimization times when working with large landscapes. Another option when working with a large landscape, is to reduce the resolution. Depending upon whether you are optimizing a single surface or multiple surfaces simultaneously, the genetic algorithms typically run for 50–300 generations. `ga` settings will vary for each run, but there will typically be 50–150 offspring (i.e. different parameter value realizations) per generation. This means that 2,500–45,000 iterations will be needed to complete the optimization. This can be a **LONG** process! If you encounter issues while executing any of these functions, or would like some other functionality incorporated, please let me know (bill.peterman@gmail.com). I am eager to make this as accessible, functional, and as useful as possible, so any and all feedback is appreciated.

## Thoughts on Optimization

There are three options which can be used when optimizing resistance surfaces with **ResistanceGA**: (1) AIC, (2) conditional  $R^2$ , or (3) log-likelihood. By default (as of version 3.0-0), the default is to optimize using seeks to optimize using  $R^2$  as the objective function. Given that the overall goal of a landscape genetics analysis is to assign resistance values that best explain genetic differentiation, it seems sensible to use  $R^2$ . Previously, AICc was used as the objective function, but it is not clear how best to determine the sample size when calculating AICc. Prior to version 3.0-0, the number of pairwise comparisons was used as the sample size. Now, sample size is equivalent to the number of populations included in your analysis. This is much more conservative, and increases in model complexity are more drastically penalized. On the topic of model complexity, this is also not a cut-and-dry assessment. **All** the mixed effects models take the form:

$$Y_{ij} = \alpha + \beta(X_{ij} - x) + \tau_i + \tau_j + e_{ij}, \quad j = 2, \dots, n; \quad i = 1, \dots, j - 1, \quad (1)$$

which is the maximum likelihood population effects parameterization (see Clarke et al., 2002). Because there is only ever a single independent variable (the vector of pairwise transformed resistance values), all models technically have the same number of parameters (*i.e.*  $k = 2$ ). However, multiple values were optimized to create these resistance values. For continuous surfaces there is a shape and a scale parameter ( $k = 3$ ), while each category within a categorical surface is estimated ( $k = \text{number of categories} + 1$ ). When multiple surfaces are optimized simultaneously, a single composite resistance is created. It is not possible to have each of these surfaces assessed as separate independent variables because of high multicollinearity among surfaces that occurs during optimization.  $k$  in multisurface models is determined as the sum of all estimated parameters plus 1 (intercept). **Again, there are no guidelines for how to determine  $n$  or  $k$  in these models. Use your best judgement and clearly articulate and justify your methods.**

Because of this uncertainty, it is now also possible to specify how  $k$  is determined: (1)  $k =$  the number of parameters in the mixed effects model (*i.e.* 2); (2)  $k =$  the total number of parameters optimized plus the intercept; (3)  $k =$  the total number of parameters optimized, plus the number of layers and the intercept. The method for evaluating  $k$  and the objective function to use during optimization can both be specified in the **GA.prep** function.

## Setup

### Install necessary software and packages

If you want to optimize using CIRCUITSCAPE, this package requires that you have CIRCUITSCAPE v4.0 or higher installed on your Windows machine. At this point in time, **ResistanceGA** has only been tested on *WINDOWS* operating systems. Ability to run on Mac or Linux systems is in testing. You will also need to have R  $\geq$  v3.0 installed. I would highly recommend installing R studio when working with R.

### Running on Linux

To run CIRCUITSCAPE on Linux (tested with Ubuntu 16.04):

1. Install CIRCUITSCAPE—Default installation directory is `/usr/local/bin/csrn.py`
  2. To call CIRCUITSCAPE from R, first change file permissions from the command line terminal (shortcut: control + alt + t) `sudo chmod 755 /usr/local/bin/csrn.py`
- \* This will allow `csrun.py` to be executed without specifying paths.

#### *R Packages*

This package consists of several wrapper functions for implementing functions from other packages, and these will all be imported when **ResistanceGA** is installed.

## Demonstrations

### Continuous surface transformations

First, install **ResistanceGA** from GitHub. This will require the `devtools` package

```
# Install 'devtools' package, if needed
if(!("devtools" %in% list.files(.libPaths()))){
  install.packages("devtools", repo = "http://cran.rstudio.com", dep = TRUE)
}

library(devtools) # Loads devtools

install_github("wpeterman/ResistanceGA") # Download package
```

Load **ResistanceGA** and clear your workspace.

```
library(ResistanceGA)
rm(list = ls())
```

There are 8 different transformations that can be applied to continuous surfaces. Since the publication of Peterman et al. (2014), I have added Reverse Ricker and Inverse-Reverse Ricker transformation to better cover parameter space. I still think that there are more flexible ways to optimize surfaces, and I'm continuing to develop these as I have time.

All of these figures were made with the `Plot.trans` function. This function returns a `ggplot` object, which

allows you to manipulate some aspects of the plot, as well as determine the resistance value at different levels of your original surface.

```
Ricker.plot <- Plot.trans(PARM=c(1.5, 200),Resistance=c(1,10),transformation="Ricker")
```

Figure 1: RickerPlot

```
# Change title of plot
Ricker.plot$labels$title<-"Ricker Transformation"
Ricker.plot

# Find original data value that now has maximum resistance
Ricker.plot$data$original[which(Ricker.plot$data$transformed==max(Ricker.plot$data$transformed))]

## [1] 2.356784
```

Figure 2: RickerPlot2

## Example Function Use

### Single surface optimization (with simulated data)

**NOTE:** The examples below include steps to generate simulated resistance surfaces and pairwise distance data.

Make a directory to write ASCII files, CIRCUITSCAPE batch files, and results. It is critical that there are **NO SPACES** in the specified directory as this will cause functions that interact with CIRCUITSCAPE to fail.

```
if("ResistanceGA_Examples"%in%dir("C:/")==FALSE)
  dir.create(file.path("C:/", "ResistanceGA_Examples"))

# Create a subdirectory for the first example
dir.create(file.path("C:/ResistanceGA_Examples/", "SingleSurface"))

# Directory to write .asc files and results
write.dir <- "C:/ResistanceGA_Examples/SingleSurface/"

# Give path to CIRCUITSCAPE .exe file
# Default = "C:/Program Files/Circuitscape/cs_run.exe"
CS.program <- paste("C:/Program Files/Circuitscape/cs_run.exe")

# If using Linux
# CS.program <- 'csrcun.py'
```

Load resistance surfaces and export as *.asc* file for use with CIRCUITSCAPE. These surfaces were made using the RandomFields package

```
data(resistance_surfaces)
continuous <- resistance_surfaces[[2]]
writeRaster(continuous, filename=paste0(write.dir, "cont.asc"), overwrite=TRUE)
```

Load the example sample location data and export as *.txt* file. This is formatted for input into CIRCUITSCAPE

```
data(samples)
write.table(samples, file=paste0(write.dir, "samples.txt"), sep="\t", col.names=F, row.names=F)

# Create a spatial points object for plotting
sample.locales <- SpatialPoints(samples[,c(2,3)])
```

Plot surface and overlay the sample points

```
plot(continuous)
plot(sample.locales, pch=16, col="blue", add=TRUE) # Add points
```

## Prepare data for optimization

Run the GA.prep and CS.prep functions

```
# Set the random number seed to reproduce the results presented
GA.inputs <- GA.prep(ASCII.dir = write.dir,
  max.cat = 500,
  max.cont = 500,
  select.trans = "A",
```

Figure 3: continuousPlot

```

seed = 555)

CS.inputs <- CS.prep(n.Pops = length(sample.locales),
  CS_Point.File = paste0(write.dir,"samples.txt"),
  CS.program = CS.program)

```

Note that `response` was not defined in `CS.prep` because it has not been made yet.

`select.trans` allows you to specify which transformations can be applied to a surface during optimization. “A” = All; “M” = Monomolecular only; “R” = Ricker only. By default, all transformations will be assessed when a continuous surface is optimized. See `GA.prep` documentation for more details.

Transform raw continuous surface using the `Resistance.tran` function to apply one of the eight transformations, and then view the transformation using `Plot.trans`. Note that `Plot.trans` returns a `ggplot2` object as well as the plot. Therefore you can manipulate and modify the plot as desired.

```

r.tran <- Resistance.tran(transformation="Monomolecular", shape=2, max=275, r=continuous)

plot.t <- Plot.trans(PARM=c(2,275), Resistance=continuous, transformation="Monomolecular")

```

Run the transformed resistance surface through CIRCUITSCAPE to get effective resistance between each pair of points. `Run_CS` returns the lower half of the pairwise resistance matrix for use with the optimization prep functions. This will be our response that we optimize on.

```
# Create the true resistance/response surface
CS.response <- Run_CS(CS.inputs=CS.inputs,GA.inputs=GA.inputs, r=r.tran)
```

**Note:** The ‘`CS.response`’ object is a simulated response variable for demonstration purposes. *When conducting your own analysis, replace ‘`CS.response`’ with the vector containing your pairwise genetic distances*

Rerun `CS.prep` including the newly created `CS.response`

```
CS.inputs <- CS.prep(n.Pops = length(sample.locales),
                    response = CS.response,
                    CS_Point.File = paste0(write.dir,"samples.txt"),
                    CS.program = CS.program)
```

With Linux, CS.program should be designated as 'csrcun.py'

Run the Single surface optimization function (SS\_optim). Running this example with the default settings took 147 iterations and ~72 minutes to complete on a computer with an Intel i7 3.4 GHz processor. The data generating values have been precisely recovered.

```
SS_RESULTS <- SS_optim(CS.inputs=CS.inputs,
                      GA.inputs=GA.inputs)
```

View the results and compare with truth

```
SS_table <- data.frame(c("Monomolecular", 2.0, 275),
                      t(SS_RESULTS$ContinuousResults[c(3:5)]))
colnames(SS_table) <- c("Truth", "Optimized")
```

```
SS_table
      Truth    Optimized
Equation Monomolecular Monomolecular
shape      2      1.999999
max      275      274.9982
```

If you get the error:

```
Error in initializePtr() :
  function 'dataptr' not provided by package 'Rcpp'
```

Reinstall the Rcpp package and execute the SS\_optim function again.

After executing the function, the console will be updated to report the time to complete each iteration as well as objective function value of each iteration. If you do not wish to view updates at each iteration of the optimization, set quiet = TRUE in GAp.prep

What the SS\_optim function does:

- \* Read each .asc file that is in the specified ASCII.dir and determines whether it is a categorical or continuous surface. A surface is considered categorical if it contains 15 or fewer unique values.
- \* Optimize each resistance surface
- \* Categorical surfaces: Each optimized value represents the resistance of that category to current flow
- \* Continuous surfaces: Each continuous surface is first rescaled so that values range from 0–10 (note that relative spacing is preserved during rescaling). The genetic algorithm then tests different combinations of the transformation equation, shape parameter value, and maximum resistance value. When the genetic algorithm has finished optimization, the optimized parameters can be passed to a second optimization function that uses nlm to fine-tune the shape and maximum value parameters (nlm = TRUE). However, this approach may lead to overfitting and the default is nlm = FALSE.
- \* Several summary outputs are generated
- \* In the 'Results' directory (located in the directory with the .asc files), a final optimized resistance .asc file has been made, along with the CIRCUITSCAPE results (.out files).
- \* Summary tables for continuous surfaces (ContinuousResults.csv), categorical surfaces (CategoricalResults.csv), and the table of all surfaces (All\_Results\_Table.csv). This table reports the optimized objective function value, AIC, marginal and conditional R<sup>2</sup>, and log likelihood.
- \* MLPE\_coeff\_Table.csv contains the model coefficients from the fitted mixed effects model for each surface
- \* In the 'Plots' directory there is a 4-panel figure with different model diagnostic plots generated from the fitted mixed effects model of each optimized resistance surface. If a continuous surface was optimized, there

is also a plot showing the relationship of the transformed resistance surface with the original data.

\* The returned object is a named list containing the tables described above.

To view the AICc response surface for the Monomolecular optimization of this surface, you can run `Grid.Search`. This function is only relevant for single continuous surfaces.

```
Grid.Results <- Grid.Search(shape=seq(1,4,by=0.1),
                           max=seq(50,500,by=75),
                           transformation="Monomolecular",
                           Resistance=continuous,
                           CS.inputs,
                           GA.inputs=GA.inputs)
```

Figure 4: GRID.Surface

You can change the color scheme and color breaks by manually recreating the response surface from the generated data [default = `topo.colors(20)`]

```
filled.contour(Grid.Results$Plot.data,
               col=rainbow(30),
               xlab="Shape parameter",
               ylab="Maximum value parameter")
```

Figure 5: GRID.Surface.update

Note that actual response surfaces tend to be slightly flatter, and the maximum value for a single surface is more difficult to identify precisely. If you were to add some random noise to the `CS.response`, the single surface optimization generally would do a good job of recovering the transformation and shape parameters, but the true maximum value may remain elusive. Occasionally the algorithm will get ‘stuck’ trying to optimize on an incorrect transformation. If this happens, rerun the optimization. Of course, you may not know that a surface wasn’t correctly optimized when using real data. For this reason, it is good practice to run all optimizations at least twice to confirm parameter estimates.

## Minimum code for running ResistanceGA

The example above outlines how the functions can be used while simulating and generating data with known parameter values. When analyzing your own data, it is not necessary to use the `r.tran` or `Run_CS` functions. You should only have to use the following functions (although you may want to change settings from defaults).

```
GA.inputs <- GA.prep(ASCII.dir=write.dir)

CS.inputs <- CS.prep(n.Pops = length(sample.locales),
                    response = CS.response,
                    CS_Point.File = paste0(write.dir,"samples.txt"),
                    CS.program = CS.program)

SS_RESULTS <- SS_optim(CS.inputs = CS.inputs,
                      GA.inputs = GA.inputs)
```

## Optimization with CIRCUITSCAPE on Linux platform

Gains in optimization speed can be achieved in two ways: 1. Run the genetics algorithm in parallel (in the `GA.prep` function set `parallel = X` where ‘X’ is the number of cores to use). 2. In the `CS.prep` function, set `parallel = TRUE` and specify `cores` to the number of cores for CIRCUITSCAPE to use when quantifying current flow across a surface.

## Optimization using least cost paths

The above optimization can also be done using cost distances calculated in `gdistance`. This approach uses least cost paths between points, so it is a simpler representation of connectivity. However, optimization using `gdistance` is ~3x faster than optimization with CIRCUITSCAPE. This optimization took 86 iterations and 7 minutes to complete when run in parallel on 4 cores (`parallel = 4` in `GA.prep`)

```
# Import data
data(resistance_surfaces)
continuous <- resistance_surfaces[[2]]

data(samples)
sample.locales <- SpatialPoints(samples[,c(2,3)])

# Set the random number seed to reproduce the results presented
# Run in parallel on 4 cores
GA.inputs <- GA.prep(ASCII.dir=continuous,
                    Results.dir=write.dir,
                    max.cat=500,
```

```

        max.cont=500,
        seed = 555,
        parallel = 4)

gdist.inputs <- gdist.prep(length(sample.locales),
                           samples=sample.locales)

# Transform resistance surface
r.tran <- Resistance.tran(transformation="Monomolecular", shape=2, max=275, r=continuous)

# Create the true resistance/response surface
gdist.response <- Run_gdistance(gdist.inputs=gdist.inputs, r=r.tran)

# Rerun `gdist.prep` to include response
gdist.inputs <- gdist.prep(n.Pops = length(sample.locales),
                           response=lower(as.matrix(gdist.response)),
                           samples=sample.locales)

# Run optimization
SS_RESULTS.gdist <- SS_optim(gdist.inputs=gdist.inputs,
                             GA.inputs=GA.inputs)

# Grid search of response surface
Grid.Results.gdist <- Grid.Search(shape=seq(1,4,by=0.1),
                                  max=seq(50,500,by=75),
                                  transformation="Monomolecular",
                                  Resistance=continuous,
                                  gdist.inputs=gdist.inputs,
                                  GA.inputs=GA.inputs)

```

---

## Simultaneous optimization of multiple surfaces

First, make a new directory to write ASCII files, CIRCUITSCAPE batch files, and results.

```

if("ResistanceGA_Examples"%in%dir("C:/")==FALSE)
  dir.create(file.path("C:/", "ResistanceGA_Examples"))

# Create a subdirectory for the second example
dir.create(file.path("C:/ResistanceGA_Examples/", "MultipleSurfaces"))

# Directory to write .asc files and results
write.dir <- "C:/ResistanceGA_Examples/MultipleSurfaces/"

```

Extract other resistance surfaces from the 'resistance\_surfaces' raster stack

```

data(resistance_surfaces)
data(samples)
sample.locales <- SpatialPoints(samples[,c(2,3)])

```

Visualize each surface:

```

plot(resistance_surfaces[[1]],main = resistance_surfaces[[1]]@data@names)
plot(sample.locales, pch=16, col="blue", add=TRUE)

```

```

plot(resistance_surfaces[[2]],main = resistance_surfaces[[2]]@data@names)
plot(sample.locales, pch=16, col="blue", add=TRUE)
plot(resistance_surfaces[[3]],main = resistance_surfaces[[3]]@data@names)
plot(sample.locales, pch=16, col="blue", add=TRUE)

```

Write all three surfaces to a directory for use with CIRCUITSCAPE and run the `GA.prep` function (needed to combine surfaces). Also write the sample location file to the “MultipleSurfaces” directory.

```
writeRaster(categorical,filename=paste0(write.dir,"cat.asc"),overwrite=TRUE)
writeRaster(continuous,filename=paste0(write.dir,"cont.asc"),overwrite=TRUE)
writeRaster(feature,filename=paste0(write.dir,"feature.asc"),overwrite=TRUE)

write.table(samples,file=paste0(write.dir,"samples.txt"),sep="\t",col.names=F,row.names=F)
```

Run `GA.prep`. In this example, the genetic algorithm will seek to maximize the log likelihood of the fitted model (`method = "LL"`).

```
GA.inputs <- GA.prep(ASCII.dir=write.dir,
  method = "LL"
  max.cat=500,
```

```
max.cont=500,  
seed = 555,  
quiet = TRUE)
```

Transform, reclassify, and combine the three resistance surfaces together. Use an “Inverse-Reverse Monomolecular” transformation of the continuous surface. Visualize this transformation using `Plot.trans`. The first value of `PARM` refers to the shape parameter, and the second value refers to the maximum value parameter. Look in the help file for `Plot.trans` for transformation names/numbers.

```
plot.t <- Plot.trans(PARM=c(3.5,400),Resistance=continuous,transformation="Reverse Ricker")
```

Combine raster surfaces together using `Combine_Surfaces`. Note that the .asc files are read in alphabetically. You can check the order of surfaces by inspecting `GA.inputs$layer.names`. First, define the parameters that will be passed to `Combine_Surfaces`.

```

PARM <- c(1, 250, 75, 6, 3.5, 150, 1, 350)

# PARM<- c(1,  # First feature of categorical
#           250, # Second feature of categorical
#           75,  # Third feature of categorical
#           6,   # Transformation equation for continuous surface
#           3.5, # Shape parameter
#           150, # Scale parameter
#           1,   # First feature of feature surface
#           350) # Second feature of feature surface

# Combine resistance surfaces
Resist <- Combine_Surfaces(PARM=PARM,
                           CS.inputs=CS.inputs,
                           GA.inputs=GA.inputs,
                           out=NULL,
                           rescale = TRUE)

# View combined surface
plot(Resist, main = "scaled composite resistance")

```

Generate new CS response surface by using Run\_CS and run CS.prep to add response

```

# Create the true resistance/response surface
CS.response <- Run_CS(CS.inputs=CS.inputs, GA.inputs=GA.inputs, r=Resist)

CS.inputs<-CS.prep(n.Pops=length(sample.locales),
                  response=CS.response,
                  CS_Point.File=paste0(write.dir,"samples.txt"),
                  CS.program=CS.program)

```

Run MS\_optim. Running this multisurface example with the default settings took 257 iterations and ~5 hours to complete on a computer with an Intel i7 3.4 GHz processor.

```

Multi.Surface_optim <- MS_optim(CS.inputs=CS.inputs,
                                GA.inputs=GA.inputs)

```

After executing the function, the console will be updated to report the time to complete each iteration as well as value of the objective function of each iteration.

What the MS\_optim function does:

- \* Read all .asc files that are in the specified ASCII.dir, makes a raster stack, and determines whether each is a categorical or continuous surface. A surface is considered categorical if it contains 15 or fewer unique values.
- \* Transformation and resistance values are chosen for each surface, all surfaces are added together, and AICc from the mixed effects model is calculated.
- \* Several summary outputs are generated
- \* In the 'Results' directory (located in the directory with the .asc files), a final optimized resistance .asc file has been made (the name is a combination of the layers optimized, separated by "."), along with the CIRCUITSCAPE results (.out files).
- \* 'Multisurface\_Optim\_Summary.txt' provides a text summary of the model parameters and results of the multisurface optimization
- \* A .csv file with the fitted MLPE model coefficients
- \* In the 'Plots' directory there is a 4-panel figure with different model diagnostic plots generated from the fitted mixed effects model of each optimized resistance surface.
- \* The GA object from the optimization is returned and can be further explored.

Figure 6: RESIST.Surface

The multisurface optimization procedure has done a pretty good job of recovering the relative data generating values. You'll notice that we have not exactly recovered the values, but that the relative relationship among surfaces is preserved (see below).

```
Summary.table <- data.frame(PARM,round(t(Multi.Surface_optim@solution),2))
colnames(Summary.table)<-c("Truth", "Optimized")
row.names(Summary.table)<-c("Category1",
                           "Category2",
                           "Category3",
                           "Transformation",
                           "Shape",
                           "Max",
                           "Feature1",
                           "Feature2")
```

Summary.table	Truth	Optimized
Category1	1.0	1.00
Category2	250.0	304.31
Category3	75.0	91.15
Transformation	6.0	6.28
Shape	3.5	3.50
Max	150.0	183.12
Feature1	1.0	1.00
Feature2	350.0	426.14

The optimized values are ~1.22 times greater than the data generating values. However, if we rescale both the true and optimized resistance surfaces to have a minimum value of 1, we see that the surfaces are identical. The values for the 3-class categorical surface are the first three values listed, the continuous surface values = 4–6, and the feature surface values = 7–8. Note that the first value for continuous surfaces identifies the transformation used (the fourth value, here), and is always rounded down (6 = Reverse Ricker). Visualize and test the equivalence of simulated and optimized resistance surfaces:

```
# Make combined, optimized resistance surface.
optim.resist <- Combine_Surfaces(PARM=Multi.Surface_optim@solution,
                                CS.inputs = CS.inputs,
                                GA.inputs = GA.inputs,
                                rescale = TRUE)

ms.stack <- stack(Resist, optim.resist)
names(ms.stack) <- c("Truth", "Optimized")
plot(ms.stack)

# Correlation between the two surfaces
pairs(ms.stack)
```

If you want to create a CIRCUITSCAPE current map from either the true or optimized surfaces, this can be done by setting `CurrentMap = TRUE` and `output = "raster"` in `Run_CS`.

```
Resist.true <- Run_CS(CS.inputs=CS.inputs,
                     GA.inputs=GA.inputs,
                     r=Resist,
                     CurrentMap=TRUE,
                     output="raster")

Resist.opt <- Run_CS(CS.inputs=CS.inputs,
                    GA.inputs=GA.inputs,
```

Figure 7: combined.plots

Figure 8: correlation.plots

```

r=optim.resist,
CurrentMap=TRUE,
output="raster")

## We can confirm that, like the resistance surfaces above,
## the CIRCUITSCAPE current maps are also correlated
cs.stack <- stack(Resist.true, Resist.opt)
names(cs.stack) <- c("Truth", "Optimized")
pairs(cs.stack)

```

Figure 9: CS\_corr.plot

The optimization often converges on a highly correlated solution, but one that results in relative resistance values that are identical to those of the simulated data. This is important to understand, and interpretation

of resistance values should be made with this fact in mind.

## Multisurface optimization using least cost paths

The multisurface optimization can also be run in parallel when using least cost paths. This can be done by setting `parallel = TRUE` or `parallel = #cores` in `GA.prep`. This example took 210 iterations to run in parallel on 4 cores, and completed in 38 minutes.

```
# Run `gdist.prep`
gdist.inputs<-gdist.prep(n.Pops=length(sample.locales),
                        samples=sample.locales)

GA.inputs <- GA.prep(ASCII.dir=resistance_surfaces,
                    Results.dir=write.dir,
                    max.cat=500,
                    max.cont=500,
                    seed = 999,
                    parallel = 4)

# Combine resistance surfaces
Resist <- Combine_Surfaces(PARM=PARM,
                          gdist.inputs=gdist.inputs,
                          GA.inputs=GA.inputs,
                          out=NULL,
                          rescale=TRUE)

# Create the true resistance/response surface
gd.response <- Run_gdistance(gdist.inputs=gdist.inputs,
                             r=Resist)

# Run `CS.prep` functions
gdist.inputs<-gdist.prep(n.Pops=length(sample.locales),
                        response=lower(as.matrix(gd.response)),
                        samples=sample.locales)

# Run `MS_optim`
Multi.Surface_optim.gd <- MS_optim(gdist.inputs=gdist.inputs,
                                   GA.inputs=GA.inputs)

summary(Multi.Surface_optim.gd)
```

**Comments on multiple surface optimization:** \* If the optimized resistance values are near the maximum value specified in `GA.prep`, it is recommended that you increase the maximum value and rerun the optimization. \* If the optimization ends very quickly (e.g., <40 iterations), you may want to increase the probability of mutation (`pmutation`) and/or the probability of crossover (`pcrossover`). These can be adjusted using `GA.prep`. I have not extensively tested these settings to determine optimal values, but found that the current defaults (`pmutation = 0.125`, `pcrossover = 0.85`) have generally worked quite well with simulated data and produced reproducible estimates with real data. Alternatively, because this is a stochastic optimization, just rerun the optimization (make sure you have not set a seed!) \* Any and all settings of the `ga` function can be adjusted or customized. The main change made from the default setting for optimization of resistance surfaces was to use the “`gareal_blxCrossover`” method. This greatly improved the search of parameter space. \* As mentioned above concerning single surface optimization: this is a stochastic optimization process and optimized values will likely differ from run to run. Despite the time involved, it is advised to run all

optimizations at least twice to confirm parameter estimates/relative relationship among resistance surfaces. \* While there is no established framework for how optimization of resistance surface can or should be done, below is a flowchart of how an analysis might proceed:

Figure 10: flowchart

## Summary

Hopefully this vignette/tutorial has demonstrated the functions present in this package and how they can be used together to optimize resistance surfaces in isolation or in combination. These methods require no *a priori* assumptions by the researcher. Optimization is conducted solely on the genetic distance data provided. The goal of this package is to make these methods accessible and useful to others. Development and advancement will continue as long as there is interest and there remains a need. Please contact me (bill.peterman@gmail.com) if you encounter issues with any of these functions, need assistance with interpretation, or would like other features added.

## Acknowledgements

A huge thanks to Grant Connette for many discussions related to development and implementation of these methods!
